Abstract. Natural spinel crystals from Ural and Pamir deposits and synthetic magnesium aluminium spinel single crystals with different stoichiometry (MgOₙAl₂O₃) grown by Verneuil method were used. The photoluminescence (PL), its excitation (PLE) and optical absorption of stoichiometric and nonstoichiometric magnesium aluminium spinel crystals containing the chromium and manganese ions and defects produced by fast neutron irradiation (fluence up to 10²⁰ cm⁻², E>0.1 MeV) are investigated. The broadening of R- and N-lines takes place in synthetic stoichiometric spinel. Structure of synthetic nonstoichiometric spinels (n>1) has to be more disordered, since in addition to the site exchange the so called stoichiometric vacancies are present in the structure. The R- and N-lines broadening takes place after spinel crystals irradiation by fast neutron too. The neutron irradiation causes increasing of the spinel inversion. Furthermore the great deviation from stoichiometry leads to the local structure of α-Al₂O₃ formation around Cr⁺⁺⁺ ions. The orange emission band at 570 nm is belonging to complex center “Mn⁺⁺⁺-F” (or F centre)

Keywords: magnesium aluminium spinel, neutron irradiation, absorption and luminescence spectra.

Introduction
Magnesium aluminium spinel is mixed oxide with high melting temperature at 2135 °C. It has good thermal and mechanical properties, high hardness and low electrical loss. MgAl₂O₄ thin film is a possible candidate for the development of integrated humidity sensors [1]. Spinel single crystals are used for substrate in integrated electronics [2], they are known as laser materials [3-6]. Since magnesium aluminium spinel is highly resistant to neutron irradiation it is considered to be a candidate material for fusion reactor application such as dielectric windows for radio – frequency heating systems and insulators for magnetic coils [7-11]. Oxide spinels have attracted great attention in the field of Earth science because of their importance as constituent minerals in many igneous and metamorphic rocks [12].

The spinel belongs to double oxides of the X²⁺(Y³⁺)₂O₄ type, where X is Mg²⁺, Fe²⁺, Mn²⁺ or other bivalent ions, and Y is Al³⁺, Fe³⁺, Cr³⁺, Mn³⁺ or other trivalent ions. Magnesium aluminium spinel MgOₙAl₂O₃ (if stoichiometric, n=1) is a cubic-type face centred crystal. The elementary cell consists of 8 formula units XY₂O₄. Oxygen ions create a close-packed arrangement with 64 tetrahedral and 32 octahedral interstices per cell. If eight bivalent ions occupy eight tetrahedral (A) sites, and 16 trivalent ones – 16 octahedral (B) sites, the spinel is described by the space symmetry group Oᵥ₁ and is called “normal”. For the “inverse” spinel, a half of the trivalent (Y) ions is located in the tetrahedral position; the other part of Y and X ions is usually statistically distributed between the octahedral positions. If we use an inversion parameter i, the chemical formula of magnesium aluminium spinel may be expressed by [Mg₁₋ₓAlₓ][MgₓAl₁₋ₓ]O₄, where [Ⅴ( )] and [Ⅳ( )] represents the tetrahedral (A sites; 8a) and the octahedral sites (B site;16d). Assuming i = 1, we obtain a formula Al[MgAl]O₄ for the inverse spinel.

Transition metal ions in magnesium aluminium spinel have been studied extensively, and their optical spectra in the infrared and visible part of a spectra are satisfactorily understood. Nevertheless, there is little information about the influence of fast neutron radiation on impurities behavior. The paper presents investigations of the of the structure and phase changes in natural and synthetic magnesium aluminium spinel crystals containing transition metal ions (Cr, Mn) and irradiated by fast neutron.
Materials and methods
Natural spinel crystals from Ural and Pamir deposits and synthetic magnesium aluminium spinel single crystals with different stoichiometry (MgO\textsubscript{n}Al\textsubscript{2}O\textsubscript{3}) grown by Verneuil method were used. Crystals labelled as ‘Mn’ have been doped with manganese. Chromium ions are used as a sensitive probe for absorption and luminescence spectra investigation. Micro (Cr, Mn, Fe) and macrocomponent (Mg, Al) quantities have been detected by the instrumental neutron activation analysis technique [13]. Concentrations of some impurities (mass %) are given in Tab.1. The Tab. 2 presents the results of the determination of the macrocomponents in the magnesium-aluminium spinels. Sample thickness was in the range of 0.5–1 mm.

Luminescence spectra of spinel crystals have been measured at liquid nitrogen temperature with an SPM-2 monochromator having a diffraction grating of 651 lines per mm. Crystals were excited by a high pressure xenon lamp (DKSEL-1000) connected to a monochromator (ZMR-1) with a quartz prism. Monitoring was carried out with a photomultiplier tube (FEU-119) using a synchronic detection method. The neutron irradiation was performed in the Latvian 5MW water-water research reactor. The fluence of fast neutrons with an energy > 0.1 MeV was in the range of 10^{14} - 10^{20} cm\textsuperscript{-2}. The accompanied γ-irradiation with average energy 1.1 MeV gave an absorption dose of 0.33 Gy. The irradiation temperature was 293 K. A cadmium filter was used for thermal neutron absorption. The optical absorption spectra were measured with a double-beam spectrophotometer “Specord M-40” (Karl Zeiss Jena) operating in the wavelength region of 200–900 nm (50000–11000 cm\textsuperscript{-1}). Optical measurements before and after irradiation were carried out at 293 and 80 K temperature.
**Results and discussion**

Fig. 1 shows the absorption spectra of MgO·Al₂O₃ single crystals before and after fast neutron irradiation. After irradiation there appears an intense absorption on the long edge and occurs the characteristic maximum at 535 nm. The intensity of this peak grows with fast neutron fluence increasing.

**Fig. 1. Absorption spectra of MgO·Al₂O₃ single crystals:**
1. before irradiation, 2. after fast neutron Φ=10¹⁶ cm⁻², 3. Φ=10²⁰ cm⁻²

The neutron irradiations of crystal with great deviation from stoichiometry (n> 2.5) have just the opposite absorption spectra (Fig. 2). Before irradiation the crystal is transparent. After irradiation at fluence Φ=10¹⁶ cm⁻² in absorption spectra there is observed intensive absorption at λ<280 nm and bands at maxima 305, 355 and 470 nm. The same effect gives neutron irradiation of the α-Al₂O₃:Cr crystal. The band’s location, which has been produced by neutron irradiation for α-Al₂O₃:Cr is similar to MgO·2.8Al₂O₃ (Fig.2, curve 4).

The photoluminescence spectra of natural and synthetic magnesium aluminium crystals with different stoichiometry are given in Fig. 3. In the natural spinel spectra (Fig.3, solid line) some zero-phonon lines were observed in the region of the Cr³⁺ ions electron transition.
\( ^2E_g \rightarrow ^4A_{2g} \): R-lines (684.7 and 684.5 nm) predetermined by Cr\(^{3+}\) ions, which replace Al\(^{3+}\) ions in the octahedral sites of the spinel lattice; N-lines (686.0, 688.2, 690.9 and 692.3 nm) related to the Cr\(^{3+}\)ions, which local symmetry differs from symmetry of sites occupied by Al\(^{3+}\) in normal spinel.

![Photoluminescence spectra of magnesium aluminium spinel.](image)

**Fig.3.** Photoluminescence spectra of magnesium aluminium spinel. Solid line – natural spinel, dashed line – synthetic crystal MgO-Al\(_2\)O\(_3\), dotted line - synthetic crystal MgO-2.8Al\(_2\)O\(_3\)

The broadening of R- and N-lines takes place in synthetic stoichiometric spinel (Fig. 3, dashed line). Structure of synthetic nonstoichiometric spinels (n>1) has to be more disordered, since in addition to the site exchange the so called stoichiometric vacancies are present in the structure. Therefore, the numbers of different versions of cation location in the 2nd coordination sphere increases. Moreover, an absence of a cation affects Cr\(^{3+}\) ion stronger than Mg\(^{2+}\) substituted for Al\(^{3+}\). The number of Cr\(^{3+}\) ions with normal arrangement becomes negligible. As a consequence, in the luminescence spectra of a nonstoichiometric spinel one can observe the highly broadened bands with rather intensive N-lines and without signs of R-lines (Fig.3, dotted line). The broadening of R- and N-lines takes place after spinel crystals irradiation with fast neutrons [14]. The photoluminescence spectra of MgO-2.8Al\(_2\)O\(_3\) crystal is shown in Fig.5b. Before irradiation (Fig. 5b, curve1) spectrum consists of so-called N-lines only [15]. After irradiation by fluence \( \Phi = 10^{16} \text{cm}^{-2} \) there appears two broad bands 470 and 580 nm (Fig.5b, curve 2). The Cr\(^{3+}\) luminescence spectrum completely changes (the luminescence spectra are observed at \( \lambda_{\text{ex}} = 400 \text{ nm} \)). Luminescence spectra of the irradiated MgO-2.8Al\(_2\)O\(_3\) crystal have been compared to that of \( \alpha \)-Al\(_2\)O\(_3\):Cr crystal. Position of the sharp lines of irradiated MgO-2.8Al\(_2\)O\(_3\) crystal coincides with the R\(_1\) and R\(_2\) lines position for \( \alpha \)-Al\(_2\)O\(_3\):Cr crystal. Taking into consideration that N – lines intensity is closely associated with the inversion parameter, it is possible to state that neutron irradiation causes increasing of the spinel inversion. Furthermore at high deviation from stoichiometry in magnesium aluminium spinel around the Cr\(^{3+}\) ions the local structure of \( \alpha \)-Al\(_2\)O\(_3\) is observed.

In absorption spectra of manganese containing nonstoichiometric magnesium-aluminium MgO-2.5Al\(_2\)O\(_3\) spinel, bands at 367, 430, 451, 550 and 610 nm are observed. Stoichiometric MgAl\(_2\)O\(_4\) single crystal has the more complex shape. Apart from the above mentioned sharp lines two broad bands with maxima 390 and 555 nm as well as 260 nm band are found out.
For Mn$^{2+}$ (3d$^5$-configuration) the net stabilization energy is zero kkal/mol [16], therefore, Mn$^{2+}$ ions equally possibly are situated in tetra- or octasites. Figure 4 shows photoluminescence excitation spectra of MgO-Al$_2$O$_3$:Mn0.1 crystal at $\lambda_{\text{lum}}$= 520 nm and $\lambda_{\text{lum}}$= 700 nm.

![Photoluminescence excitation spectra](image)

**Fig.4. Photoluminescence excitation spectra of MgO-Al$_2$O$_3$:Mn0.1 crystal:**

1 - $\lambda_{\text{lum}}$= 520 nm, 2 - $\lambda_{\text{lum}}$= 700 nm

The spectra obtained at 520 nm showed two sharp lines at 433 and 455 nm, but for $\lambda_{\text{lum}}$= 700 nm there are observed two broad lines 565 and 430 nm, which correspond to energies of the $^4A_{2g} \rightarrow ^4T_{2g}$ and $^4A_{2g} \rightarrow ^4T_{1g}$ transition of Cr$^{3+}$ ions. Shapes of the excitation spectra of stoichiometric and nonstoichiometric spinel are identical. But the relationship between band intensity and manganese concentration differs from sample to sample according to its composition. In contrast to synthetic spinel an emission band with a maximum at 625 nm has been found in natural spinel (dark and middle). An emission band with fine structure around 640 nm has been revealed in natural lilac colored spinel in addition to the band at 510 nm [17]. Photoluminescence spectra of MgO-Al$_2$O$_3$: crystal containing 0.1 mass% of manganese is given in Fig.5a. Before irradiation spectra contain only Cr$^{3+}$ impurity bands. After irradiation there appears a broad emission band, which spreads from 500 to 800 nm ($\lambda_{\text{ex}}$= 470 nm). Band at 520 nm is connected with Mn$^{2+}$ ions occupying tetrahedral site in spinel structure. Green emission has been observed in synthetic stoichiometric and nonstoichiometric spinel with manganese impurity [18].

After irradiation a band at 570 nm appears in photoluminescence spectra of MgO-Al$_2$O$_3$: crystal containing 0.1 mass% of manganese (Fig. 5a). This band appears only at low temperature in pattern containing manganese. Evidently, that the broad emission line 500-800 nm is connected with intrinsic defects, but peak 570 nm - with complex centers, because it appears after neutron irradiation only in the crystal containing manganese impurity.

A model which explains the observed features is that Mn$^{2+}$ impurity ions are perturbed by presence of a nearby F or F$^+$ center (anion vacancies in the spinel can capture one or two electron to form F$^+$ and F centers [19]). The presence of a nearby F or F$^+$ center may modify the environment at the Mn$^{2+}$ impurity site to produce an effective increase in the crystal field. In additional to the shift in energy, the perturbation induced by the F or F$^+$ center can increase the oscillator strength by introducing odd components to the crystal field, or by exchange coupling between the F or F$^+$ center and the Mn$^{2+}$ impurity. The enhancement of the oscillator strength by the exchange interaction has been previously observed between F centers and transition metal impurity ions in MgF$_2$, MgAl$_2$O$_4$ and MgO [20-24]. As the concentration of F and F$^+$ centers increased, the number of perturbed manganese sites also increased, so that the

Summary
The photoluminescence (PL), its excitation (PLE) and optical absorption of stoichiometric and nonstoichiometric magnesium aluminium spinel crystals containing chromium and manganese ions and defects produced with fast neutron irradiation fluence up to 10^{20} cm^{-2} (E>0.1 MeV) are investigated. Natural spinel crystals from Ural and Pamir deposits and synthetic magnesium aluminium spinel single crystals with different stoichiometry (MgOnAl₂O₃) grown by Verneuil method were used. Micro (Cr, Mn, and Fe) and macro component (Mg, Al) quantities have been detected by instrumental neutron activation analysis technique. Chromium ions are used as a sensitive probe for absorption and luminescence spectra investigation.

In the natural spinel spectra some zero-phonon lines were observed in the region of the Cr^{3+} ions electron transition 2E_g→4A_2g: R-lines predetermined by Cr^{3+} ions, which replace Al^{3+} ions in the octahedral sites of the spinel lattice; N-lines related to the Cr^{3+}ions the local symmetry, which differs from symmetry of sites occupied by Al^{3+} in normal spinel. The broadening of R- and N-lines takes place in synthetic stoichiometric spinel. The R- and N-lines broadening takes place after spinel crystals irradiation by fast neutrons, too. Taking into consideration that N – lines’ intensity is closely associated with the inversion parameter, it is possible to state that neutron irradiation causes increasing of spinel inversion. Furthermore the great deviation from stoichiometry leads to the local structure of α-Al₂O₃ formation around Cr^{3+} ions.

The orange emission is attributing to Mn^{2+} in octahedral coordination, it is possible to assume that the band at 570 nm belongs to a complex center “Mn^{2+}-F” (or F centre)”.
